Perhaps the most important property of the fundamental group is that a continuous map between spaces induces a homomorphism between groups. (This implied, for instance, that homeomorphic spaces have isomorphic  $\pi_1$ ). The same is true for homology groups, for essentially the same reason. Given a map  $f : X \rightarrow Y$ , there is an induced map  $f_\# : C_n(X) \rightarrow C_n(Y)$  defined by postcomposition; for a singular simplex  $\sigma$ ,  $f_\#(\sigma) = f \circ \sigma$ , and we extend the map linearly. Since  $f \circ (g|_A) = (f \circ g)|_A$  (postcomposition commutes with restriction of the domain),  $f_\#$  commutes with  $\partial : f_\#(\partial\sigma) = \partial(f_\#(\sigma))$ . A homomorphism between chain complexes (i.e., a sequence of such maps, one for each chain group) which commutes with the boundary maps in this way, is called a *chain map*. A chain map, such as  $f_\#$ , therefore, takes cycles to cycles, and boundaries to boundaries, and so  $f_\# : Z_i(X) \rightarrow Z_i(Y)$  (which is linear, hence a homomorphism) induces a homomorphism  $f_* : H_i(X) \rightarrow H_i(Y)$  by  $f_*[z] = [f_\#(z)]$ . Since it is defined by composition with singular simplices, it is immediate that, for a map  $g : Y \rightarrow Z$ ,  $(g \circ f)_* = g_* \circ f_*$ . And since the identity map  $I : X \rightarrow X$  satisfies  $I_\# = Id$ , so  $I_* = Id$ , homeomorphic spaces have isomorphic homology groups.

Another important property of  $\pi_1$  is that homotopic maps give the same induced map (after correcting for basepoints). This is also true for homology; if  $f \sim g : X \rightarrow Y$ , then  $f_* = g_*$ . The proof, however, is not quite as straightforward as for homotopy. And it requires some new technology; the chain homotopy. A chain homotopy  $H$  between the chain complexes  $f_\#, g_\# : C_*(X) \rightarrow C_*(Y)$  is a sequence of homomorphisms  $H_i : C_i(X) \rightarrow C_{i+1}(Y)$  satisfying  $H_{i-1}\partial_i + \partial_{i+1}H_i = f_\# - g_\# : C_i(X) \rightarrow C_i(Y)$ . The existence of  $H$  implies that  $f_* = g_*$ , since for an  $i$ -cycle  $z$  (with  $\partial_i(z) = 0$ ) we have  $f_*[z] - g_*[z] = [f_\#(z) - g_\#(z)] = [H_{i-1}\partial_i(z) + \partial_{i+1}H_i(z)] = [H_{i-1}(0) + \partial_{i+1}(w)] = [\partial_{i+1}(w)] = 0$ . And the existence of a homotopy between  $f$  and  $g$  implies the existence of a chain homotopy between  $f_\#$  and  $g_\#$ . This is because the homotopy gives a map  $H : X \times I \rightarrow Y$ , which induces a map  $H_\# : C_{i+1}(X \times I) \rightarrow C_{i+1}(Y)$ . Then we pull, from our back pocket, a *prism map*  $P : C_i(X) \rightarrow C_{i+1}(X \times I)$ ; the composition  $H_\# \circ P$  will be our chain homotopy. The prism map takes a (singular)  $i$ -simplex  $\sigma$  and sends it to a sum of singular  $(i+1)$ -simplices in  $X \times I$ . and the way we define it is to take the  $i$ -simplex  $\Delta^i$ , and taking it to  $\Delta^i \times I$  (i.e., a *prism*), and thinking of this as a sum of  $(i+1)$ -simplices. Using the map  $\sigma' = \sigma \times Id : \Delta^i \times I \rightarrow X \times I$  restricted to each of these  $(i+1)$ -simplices yields the prism map. Now, there are many ways of decomposing a prism into simplices, but we need to be careful to choose one which restricts well to each of the faces of  $\Delta^i$ , in order to get the chain homotopy property we require. In the end, what this requires is that the decomposition, when restricted to any face of  $\Delta^i$  (which we think of as a copy of  $\Delta^{i-1}$ ), is the same as the decomposition we would have applied to a prism over an  $(i-1)$ -simplex. After some exploration, we are led to the following formulation.

If we write  $\Delta^n \times \{0\} = [v_0, \dots, v_n]$  and  $\Delta^n \times \{1\} = [w_0, \dots, w_n]$ , then we can decompose  $\Delta^n \times I$  as the  $(n+1)$ -simplices  $[v_0, \dots, v_i, w_i, \dots, w_n]$ . We then define  $P(\sigma) = \sum (-1)^i \sigma'|_{[v_0, \dots, v_i, w_i, \dots, w_n]}$ . A routine calculation verifies that  $(\partial P + P\partial)(\sigma) = \sigma'|_{[w_0, \dots, w_n]} - \sigma'|_{[v_0, \dots, v_n]}$ ; Composing with  $H_\#$  yields our result.

Consequently, for example, homotopy equivalent spaces have isomorphic (reduced) homology groups; homotopy equivalences induce isomorphisms. So all contractible spaces have trivial reduced homology in all dimensions, since they are all homotopy to a point. If we think of a cell complex as a collection of disks glued together, this lends some hope that we can compute their homology groups, since we can compute the homology of the building blocks. Our next goal is to make turn this idea into action; but we need another tool, to frame our answer in the best way possible.

**Exact sequences:** Most of the fundamental properties of homology groups are described in terms of exact sequences. A sequence of homomorphisms  $\dots \xrightarrow{f_{n+1}} A_n \xrightarrow{f_n} A_{n-1} \xrightarrow{f_{n-1}} A_{n-2} \rightarrow \dots$  of abelian groups is called *exact* if  $\text{im}(f_n) = \text{ker}(f_{n-1})$  for every  $n$ . In most cases, we get the most mileage out of an exact sequence when some of the groups are trivial;  $0 \rightarrow A \xrightarrow{f} B$  is exact  $\Leftrightarrow f$  is injective, and  $A \xrightarrow{f} B \rightarrow 0$  is exact  $\Leftrightarrow f$  is surjective. An exact sequence  $0 \rightarrow A \rightarrow B \rightarrow C \rightarrow 0$  is called a *short exact sequence*.

The main tool we will use turns a family of short exact sequences of chain maps between three chain complexes into a single *long exact homology sequence*. Given chain complexes  $\mathcal{A} = (A_n, \partial)$ ,  $\mathcal{B} = (B_n, \partial')$ , and  $\mathcal{C} = (C_n, \partial'')$  and short exact sequences of chain maps (i.e.,  $\partial' i_n = i_n \partial$ ,  $\partial'' j_n = j_n \partial'$ )

$0 \rightarrow A_n \xrightarrow{i_n} B_n \xrightarrow{j_n} C_n \rightarrow 0$  there is a general result which provides us with a long exact sequence

$$\cdots \xrightarrow{\partial} H_n(\mathcal{A}) \xrightarrow{i_*} H_n(\mathcal{B}) \xrightarrow{j_*} H_n(\mathcal{C}) \xrightarrow{\partial} H_{n-1}(\mathcal{A}) \xrightarrow{i_*} \cdots$$

Most of the work is in defining the “boundary” map  $\partial$ . Given an element  $[z] \in H_n(\mathcal{C})$ , a representative  $z \in C_n$  satisfies  $\partial''(z) = 0$ . But  $j_n$  is onto, so there is a  $b \in B_n$  with  $j_n(b) = z$ . Then  $i_{n-1} \partial'(b) = \partial'' j_n(b) = 0$ , so  $\partial'(b) \in \ker(j_{n-1} = \text{im}(i_{n-1}))$ . So there is an  $a \in A_{n-1}$  with  $i_{n-1}(a) = \partial'(b)$ . But then  $i_{n-2} \partial(a) = \partial' i_{n-1}(a) = \partial' \partial'(b) = 0$ , so, since  $i_{n-2}$  is injective,  $\partial a = 0$ , so  $a \in Z_{n-1}(\mathcal{A})$ , and so represents a homology class  $[a] \in H_n(\mathcal{A})$ . We define  $\partial([z]) = [a]$ .

To show that this is well-defined, we need to show that the class  $[a]$  we end up with is independent of the choices made along the way. The choice of  $a$  was not really a choice;  $i_{n-1}$  is, by assumption, injective. For  $b$ , if  $j_n(b) = z = j_n(b')$ , then  $j_n(b - b') = 0$ , so  $b - b' = i_n(w)$  for some  $w \in A_n$ . Then  $\partial' b' = \partial' b - \partial' i_n(w) = \partial' b - i_{n-1} \partial(w)$ , so choosing  $a' = a - \partial(w)$  we have  $i_{n-1}(a') = \partial'(b')$ . But then  $[a'] = [a - \partial w] = [a] - [\partial w] = [a]$ . Finally, there is actually a choice of  $z$ ; if  $[z] = [z']$ , then  $z' = z + \partial'' w$  for some  $w \in C_{n+1}$ ; but then choosing  $b', w'$  with  $j_n(b') = z'$ ,  $j_{n+1}(w') = w$ , we have

$$\partial'' w = \partial'' j_{n+1}(w') = j_n \partial'(w'), \text{ so}$$

$z' = z + \partial'' w = j_n(b + \partial' w')$ , so we may choose  $b' = b + \partial' w'$  (since the result is independent of this choice!), then since  $\partial' b' = \partial' b$  everything continues the same.

Now to exactness! We need to show three (types of) equalities, which means six containments. Three (image contained in kernel) are shown basically by showing that compositions of two consecutive homomorphisms are trivial.  $j_n i_n = 0$  immediately implies  $j_* i_* = 0$ . From the definition of  $\partial$ ,  $i_* \partial[z] = [i_n(a)] = [\partial'(b)] = 0$ , and  $\partial j_*[z] = \partial[j_n(z)] = [a]$ , where  $i_{n-1}(a) = \partial'(z) = 0$ , so  $a = 0$  (since  $i_{n-1}$  is injective), so  $[a] = 0$ .

For the opposite containments, if  $j_*[z] = [j_n(z)] = 0$ , then  $j_n(z) = \partial'' w$  for some  $w$ . Since  $j_{n+1}$  is onto,  $w = j_{n+1}(b)$  for some  $b$ . Then  $j_n(z - \partial' b) = \partial'' w - \partial'' j_{n+1} b = 0$ , so  $z = \partial' b = i_n(a)$  for some  $a$ , so  $i_*[a] = [z - \partial' b] = [z]$ . So  $\ker j_* \subseteq \text{im } i_*$ . If  $i_*[z] = 0$ , then  $i_n(z) = \partial' w$  for some  $w \in B_{n+1}$ . Setting  $c = j_{n+1}(w)$ , then  $\partial'' c = j_n \partial' w - i_n i_n(Z) = 0$ , so  $[c] \in H_{n+1}(\mathcal{C})$ , and computing  $\partial[c]$  we find that we can choose  $w$  for the first step and  $z$  for the second step, so  $\partial[c] = [z]$ . So  $\ker j_n \subseteq \text{im } \partial$ . Finally, if  $\partial[z] = 0$ , then  $z = j_n(b)$  for some  $b$ , and  $\partial' b = i_{n-1}(a)$  with  $[a] = 0$ , i.e.,  $a = \partial w$  for some  $w$ . So  $\partial' b = i_{n-1} \partial w = \partial' i_n w$ . But then  $\partial'(b - i_n w) = 0$ , and  $j_n(b - i_n w) = z - 0 = z$ , so  $z \in \text{im}(j_n)$ , so  $[z] \in \text{im}(j_*)$ . So  $\ker \partial \subseteq \text{im}(j_n)$ . Which finishes the proof!

Now all we need are some new chain complexes. To start, we build the singular chain complex of a pair  $(X, A)$ , i.e., of a space  $X$  and a subspace  $A \subseteq X$ . Since as abelian groups we can think of  $C_n(A)$  as a subgroup of  $C_n(X)$  (under the injective homomorphism induced by the inclusion  $i : A \rightarrow X$ ) we can set  $C_n(X, A) = C_n(X)/C_n(A)$ . Since the boundary map  $\partial_n : C_n(X) \rightarrow C_{n-1}(X)$  satisfies  $\partial_n(C_n(A)) \subseteq C_{n-1}(A)$  (the boundary of a map into  $A$  maps into  $A$ ), we get an induced boundary map  $\partial_n : C_n(X, A) \rightarrow C_{n-1}(X, A)$ . These groups and maps  $(C_n(X, A), \partial_n)$  form a chain complex, whose homology groups are the *singular relative homology groups of the pair*  $(X, A)$ . To be a cycle in relative homology, you need to have a representative  $z$  with  $\partial z \in C_{n-1}(A)$ , i.e., you are a chain with boundary in  $A$ . To be a boundary, you need  $z = \partial w + a$  for some  $w \in C_{n+1}(X)$  and  $a \in C_n(A)$ , i.e., you *cobound* a chain in  $A$  ( $\partial w = z - a$ ). Note that the relative homology of the pair  $(X, \emptyset)$  is just the ordinary homology of  $X$ ; we aren't modding out by anything.

There is a reduced relative homology as well, since we can augment with the same map (1-simplices always have 2 ends!), but in this case it has (essentially) no effect;  $\tilde{H}_i(X, A) \cong H_i(X, A)$  for all  $i$  unless  $A = \emptyset$ , in which case we lose the  $\mathbb{Z}$  in dimension 0 that we expect to.

The inclusion  $i_n$  and projection  $p_n$  maps give us short exact sequences  $0 \rightarrow C_n(A) \rightarrow C_n(X) \rightarrow C_n(X, A) \rightarrow 0$ , and since the boundary on chains in  $X$  restricts to the boundary on  $A$  and induces the boundary on  $(X, A)$ ,  $i_n$  and  $p_n$  are chain maps. So we get a long exact homology sequence

$$\cdots \rightarrow H_n(A) \rightarrow H_n(X) \rightarrow H_n(X, A) \rightarrow H_{n-1}(A) \rightarrow H_{n-1}(X) \rightarrow \cdots$$

There is also a long exact sequence of a triple  $(X, A, B)$ , where by triple we mean  $B \subseteq A \subseteq X$ . From the short exact sequences  $0 \rightarrow C_n(A, B) \rightarrow C_n(X, B) \rightarrow C_n(X, A) \rightarrow 0$  (i.e.,  $0 \rightarrow C_n(A)/C_n(B) \rightarrow C_n(X)/C_n(B) \rightarrow C_n(X)/C_n(A) \rightarrow 0$ ) we get the long exact sequence

$$\cdots \rightarrow H_n(A, B) \rightarrow H_n(X, B) \rightarrow H_n(X, A) \rightarrow H_{n-1}(A, B) \rightarrow H_{n-1}(X, B) \rightarrow \cdots$$

From these humble beginnings we can do some meaningful calculations! First note that if  $X$  is contractible then  $\tilde{H}_i(X) = 0$  for every  $i$ .
